

# Class 1: Alpha, Beta, and the CAPM

Financial Markets, Spring 2021, SAIF

**Jun Pan**

**Shanghai Advanced Institute of Finance (SAIF)  
Shanghai Jiao Tong University**

**May 22-23, 2021**

# Outline

- The risk that matters:
  - ▶ The central insight of the CAPM is that investors are only rewarded for bearing systematic risk.
  - ▶ Idiosyncratic risk, uncertainty that can be diversified away, deserves no risk premium.
- Running regressions to estimate the CAPM alpha and beta:
  - ▶ We will use the aggregate stock returns,  $R_t^M$ , as a proxy for the systematic risk.
  - ▶ The key regression to be used throughout the semester for any portfolio  $i$ :

$$R_t^i - r_f = \alpha + \beta (R_t^M - r_f) + \epsilon_t.$$

- ▶ Key concepts:  $\alpha$ ,  $\beta$ , R-squared, standard error, and t-statistics.

# The CAPM

- The CAPM identifies one single portfolio, the market portfolio  $R^M$ , to be the only source of risk that matters.
- The market risk premium =  $E(R^M) - r_f$ , where  $r_f$  is the riskfree rate.
- So far, our estimate for  $E(R^M)$  is around 12% per year (and very noisy). The riskfree rate is on average 4% per year. So a good estimate for the market risk premium is around 8%.
- The risk of each individual stock, say GE, is measured *not by its own volatility* but by its *exposure* to the market risk:

$$\beta^{GE} = \frac{\text{covariance}(R^{GE}, R^M)}{\text{variance}(R^M)}$$

- The reward is proportional to the risk:

$$E(R^{GE}) - r_f = \beta^{GE} \times (E(R^M) - r_f)$$

## Running Regression to Estimate the CAPM $\beta$ :

- Identify an index as the market portfolio. Typical choice: the CRSP value-weighted index (e.g., the academics), the S&P 500 index (e.g., Merrill Lynch's beta book), and the NYSE index (e.g., Value-line).
- Identify the stock or portfolio of interest.
- Collect time-series of returns:
  - ▶ For the market portfolio:  $R_t^M$ ,  $t = 1, 2, 3, \dots T$ .
  - ▶ For the test portfolio:  $R_t^{GE}$ ,  $t = 1, 2, 3, \dots T$ .
- Run the following regression (typically monthly data over a five-year rolling window):

$$R_t^{GE} - r_f = \alpha + \beta (R_t^M - r_f) + \epsilon_t$$

## Two Sources of Uncertainty in a Stock

- By running this regression, we break the total uncertainty in a stock into two components:

$$R_t^{GE} - r_f = \alpha + \beta (R_t^M - r_f) + \epsilon_t$$

- ▶ One is due to its exposure to the market portfolio:  $\beta (R_t^M - r_f)$ .
  - ▶ The other is idiosyncratic, as captured by the regression residual  $\epsilon_t$ .
- By construction, the residual of a regression is uncorrelated with the explanatory variable:  $\text{cov}(R_t^M, \epsilon_t) = 0$ .
- The R-squared tells us how much of GE's variance can be explained by the variance in the market portfolio:

$$\text{R-squared} = \frac{\beta^2 \text{var}(R^M)}{\text{var}(R^{GE})} = \frac{\beta^2 \text{var}(R^M)}{\beta^2 \text{var}(R^M) + \text{var}(\epsilon)}$$

## The CAPM $\alpha$

- If you re-arrange that regression equation, you get

$$\alpha = R_t^{GE} - r_f - \beta (R_t^M - r_f) - \epsilon_t .$$

- Taking expectations on both sides, we have

$$\alpha = E (R_t^{GE} - r_f) - \beta E (R_t^M - r_f) ,$$

$\alpha$  is the *expected* excess stock return, after taking out the reward associated with the systematic component.

- So testing the CAPM pricing formula is the same as testing whether or not  $\alpha$  is zero.
- Conversely, if we can construct many portfolios with positive and statistically significant  $\alpha$ 's, then the CAPM pricing formula is under a severe challenge.

## Using t-stat

$$\text{t-stat} = \frac{\text{estimate}}{\text{s.e.}}$$

- In finance, we often use historical data to estimate financial models. The model parameters (e.g.,  $\alpha$  and  $\beta$ ) are always estimated with noise.
- The standard errors and t-stat inform us on the precision. We can then decide whether or not to take the estimates seriously.
- As a rule of thumb, we take an estimate seriously if the absolute value of its t-stat is larger than 1.96:

$$|\text{t-stat}| \geq 1.96$$

- If it is less than 1.96, then we don't take it as seriously: statistically insignificant from zero.

## Alpha, Beta, and R-Squared

Ticker	Start	mean (%)	std (%)	Alpha (%)	Beta	R2 (%)
GE	192701	1.14 [4.58]	7.98	0.13 [0.86]	1.18 [43.62]	65.12
AAPL	198101	2.28 [3.10]	14.19	1.13 [1.73]	1.45 [10.25]	22.08
BRK	197611	2.04 [5.79]	7.21	1.23 [3.87]	0.68 [9.80]	18.69
ONXX	199606	3.10 [1.71]	24.72	2.26 [1.31]	1.52 [4.38]	9.36
GOOG	200409	2.72 [2.23]	11.46	2.15 [2.00]	1.10 [5.04]	22.63

All time series end on 201112

## Alpha, Beta, and R-Squared

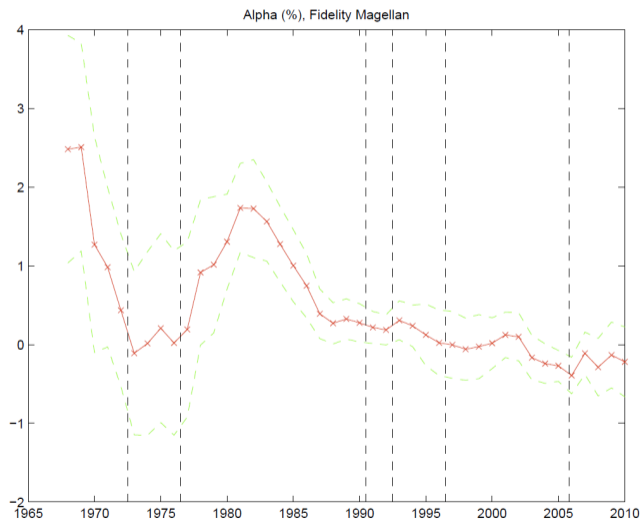

Ticker	Start	mean (%)	std (%)	Alpha (%)	Beta	R2 (%)
GE	200409	0.03 [0.03]	9.01	-0.64 [-1.02]	1.38 [10.88]	57.63
AAPL	200409	4.30 [3.54]	11.39	3.68 [3.60]	1.25 [6.06]	29.70
BRK	200409	0.45 [0.80]	5.27	0.12 [0.24]	0.44 [4.22]	16.99
ONXX	200409	1.76 [0.85]	19.43	1.24 [0.62]	0.97 [2.37]	6.08
GOOG	200409	2.72 [2.23]	11.46	2.15 [2.00]	1.10 [5.04]	22.63

All time series start on 200409 and end on 201112

## Wall Street's Search for Alpha

- Searching for investment opportunities with positive alpha is the goal of every active fund manager.
- One thing for sure, without taking on idiosyncratic risk  $\epsilon$ , a portfolio manager's alpha is always zero. So effectively, he is hoping to get  $\alpha$  as a reward for holding  $\epsilon_t$ .
- In the world of the CAPM, this is impossible.
- So do active fund managers actually provide positive  $\alpha$ ? We need to look into the data to find out.

# Alpha of a Mutual Fund

# Alpha of Hedge Funds

## Warren Buffett and Berkshire Hathaway

Monthly returns of BRK.A from November 1976 through December 2008. The sample mean is 1.69% and the standard deviation is 7.29%.

alpha	1.36%	1.11%
	[4.04]	[3.38]
Market beta	0.71	0.93
	[9.50]	[11.60]
SMB beta		-0.26
		[-2.42]
HML beta		0.58
		[4.67]
$R^2$	19.10%	26.33%

## Subsample Analysis

	First Half 197611-199212		Second Half 199301-200812	
alpha	1.83% [3.69]	1.49% [2.99]	0.84% [1.91]	0.69% [1.74]
Market beta	0.93 [8.70]	1.04 [8.38]	0.46 [4.53]	0.70 [7.16]
SMB beta		0.31 [1.54]		-0.57 [-4.83]
HML beta		0.58 [2.64]		0.44 [3.18]
$R^2$	28.28%	31.68%	9.72%	29.81%
